## Section Highlights

- Mean household landholding size is 5.2 acres, the median is 3 acres; $70 \%$ of households own less than 5 acres total.
- Landholding size varies significantly by zone, with Western zone having the largest landholdings at 8.5 acres, and Zanzibar the lowest at 2 acres.
- The average number of plots cultivated is 2.3 per household, for those households that cultivated land.
- The most commonly cultivated crop was maize, with $83 \%$ of households cultivating at least one plot of maize. Cassava ( $35 \%$ ) and beans ( $34 \%$ ) were the next most commonly cultivated crops.
- The number of crops grown by households also varies by zone, with Lake zone having the most crops grown per household (an average of six) and Zanzibar and Central zone the fewest (just over three).
- $17 \%$ of households in the sample reported cultivating rice.
- $57 \%$ of households cultivated in the long rainy season only; $39 \%$ of households cultivated in both the short and long rainy seasons.
- $92 \%$ of household reported owning a hoe, but just under $8 \%$ owned a plough.
- Crops cultivated were relatively similar between male- and female-headed households, although maleheaded households were more likely to grow cassava, millet, and mangos than female-headed households
- Average labor productivity at the national level in the long rainy season was $\$ 1.52$ per day of work, while average land productivity was $\$ 45.50$ per acre.
- Paddy had the highest land and labor productivity.
- Land productivity and yields for maize, paddy, and cassava tended to be higher in households with smaller landholdings and on smaller plots.
- Intercropping is common: $63 \%$ of all plots are intercropped. Labor productivity tends to be higher on intercropped plots.
- Roughly $40 \%$ of plots reported some pre-harvest losses, with damage by animals being the most common reason for losses.
- Lack of agricultural equipment and tools were the most commonly cited reasons why farmers did not plant the full area of a plot. $12 \%$ of maize farmers and $13 \%$ of paddy farmers reported this constraint in the long rainy season.

## Basic Farm Characteristics

Of the total 3,265 households surveyed in the LSMS, 2,474 households completed the agricultural module. Households completed the agricultural module if they owned or cultivated a plot, if they owned livestock, and/or if they participated in aquaculture. Of the 2,474 agricultural households, 80 households had livestock, but no plots, and 20 households participated in aquaculture but did not own or cultivate a plot. The remaining 2,374 households cultivated or owned a plot. However, of those that reported cultivating or owning a plot, only 2,298 also reported a plot size and plot data for their plot.

On average, households that owned and/or cultivated at least 1 plot cultivated 2.3 plots with a total landholding size of 5.2 acres. On this land they grew 4.7 different crops spread between the long and short rainy seasons and including fruit and permanent crops. As shown in Figure 1, while a few households cultivated five or more plots, more than $65 \%$ cultivated only one or two plots.

Figure 1: Distribution of Number of Plots Owned and/or Cultivated by Household, N=2298*

* Households that own or cultivate at least one plot

Questions st2q1, st2q2, st2q3, st2q4, s2aq4, \& s2bq4
Figure 2 shows the distribution of household landholding size is skewed toward smaller acreages. Although the mean is 5.2 acres, the median is 3 acres and $70 \%$ of households own less than 5 acres total.

Figure 2
Distribution of Household Landholding

${ }^{*} \mathrm{~N}=2246$, to maintain a scale on the chart that can be easily viewed, 49 observations above 20 acres are not shown

Questions s2aq4 \& s2bq9
Most households grow a variety of crops (Figure 3). As mentioned above, the mean number of crops grown was 4.7 crops per household. Fifty percent of households grew four or more crops, and $25 \%$ of households grew more than six.

Figure 3: Distribution of Number of Crops Grown by Household, N=2298*

* Households that own or cultivate at least one plot

As shown in Figure 4, the majority of households only cultivated plots during the long rainy season. ${ }^{1}$ About $39 \%$ of households cultivated during both the long and short rainy seasons, and less than $5 \%$ cultivated only during the short rainy season or did not cultivate their plot at all. Of those plots cultivated during the short rainy season, about $42 \%$ were from the Lake zone, $29 \%$ were in the Northern zone, $12 \%$ were in the Eastern zone, and $9 \%$ were in the Western zone. Appendix $A$ includes full descriptive statistics for basic farm characteristics.

[^0]Figure 4: Households Cultivating Plots by Season

* $N=2,230$ households that owned and/ or cultivated a plot

As shown in Figure 5, cultivation was by far the most common use for plots during the long rainy season with $85 \%$ reported as cultivated and $11 \%$ left fallow. Almost half of plots were reported as fallow during the short rainy season, and only about a quarter were cultivated. However, these findings could be due in part to the fact that some people living in areas without a short rainy season reported uses for their plots in both rainy seasons. For example, there were 475 observations of plot uses for the short rainy season in the Southern Zone, which does not have a short rainy season. Ninety-five percent of these plots were reported as fallow during the short rainy season.

Figure 5: Uses of Plots During the Long Rainy Season

*Question s3aq3
The average distance from plots to the market was 8.2 km . Figure 6 shows the distribution of the distance of plots to the market (What is the distance from [PLOT] to: market?).

Figure 6
Distribution of Distance from Plots to Market Long Rainy Season Plots

${ }^{*} N=5071$, to maintain a scale on the chart that can be easily viewed, 49 observations above 40 km are not shown

Figure 7
Distribution of Household Average Distance from Plots to Market Long Rainy Season Plots

${ }^{*} \mathrm{~N}=2262$, to maintain a scale on the chart that can be easily viewed, 18 observations above 40 km are not shown

## *Question s3aq2_3

While most households that owned or cultivated a plot owned hoes ( $92 \%$ ), ownership of other farm implements was rare (see Table 1) (How many [TTEMS] does your household own?).

Table 1: Proportion of Agricultural Households that Own Farm Implements

|  | Estimated Proportion who Own Implement* | Mean Number Owned | Observations |
| :---: | :---: | :---: | :---: |
| Hoes | 92.1\% | 3.1 | 2077 |
| Plough etc. | 7.7\% | 1.3 | 144 |
| Spraying machine | 4.5\% | 1.3 | 100 |
| Water pumping set $\dagger$ | 0.9\% | - | 23 |

| Fertilizer distributor | 0.0\% | - |  |
| * $N=2297$ bouseholds that own or cultivate at least one plot $\dagger$ Insufficient observations to calculate reliable mean for number owned |  | Questions snoode ór snq1 |  |

## Male- and Female-Headed Households

Male-headed households on average had more plots, larger household landholding size and grew more crops than female-headed households (See Table 2). Appendix C includes full descriptive statistics comparing priority crop cultivation and basic farm characteristics of male- and female-headed households.

Table 2: Basic Farm Characteristics of Male- and Female-Headed Households

***Statistically significant at the .01 level

## Analysis by Zone

As shown in Figure 8, the average household landholding size varied substantially by zone (ranging from 2.0 acres in Zanzibar to 8.5 acres in the Western zone). However, the average number of plots owned was fairly similar across zones, ranging from 1.9 plots in the Northern zone to 2.6 in the Southern Highlands. The average number of crops grown by household varied from just over three in Zanzibar to slightly more than six in the Lake zone. Table 3 shows the means displayed in Figure 8 and Appendix E includes confidence intervals.

Figure 8: Basic Farm Characteristics by Zone

[^1]Table 3: Mean Basic Farm Characteristics by Zone

|  | Mean <br> Household <br> Landholding <br> (Acres)*** | Mean <br> Number of <br> Plots*** | Mean Number of <br> Crops Grown** | Observations |
| :--- | :--- | :--- | :--- | :--- |
| Western | 8.5 | 2.4 | 5.2 | 136 |
| Central | 6.2 | 2.5 | 3.5 | 195 |
| Southern | 5.4 | 2.5 | 5.1 | 343 |

## BMGF Priority Crops in Tanzania

Basic descriptive analysis was conducted for the 10 BMGF priority crops in Tanzania as well as mangoes, which were cultivated by $33 \%$ of agricultural households. The 10 BMGF priority crops included are: maize, paddy (rice), sorghum, millet, beans, cowpeas, sweet potatoes, yams, groundnuts, and cassava. Table 4 shows the estimated proportion of agricultural households that cultivated each priority crop. Maize was most commonly cultivated, followed by cassava, beans, and mango.

Table 4: Households Cultivating Priority Crops ( $\mathrm{N}=2298$ )

|  | Estimated Proportion of <br> Crop |  |
| :--- | :--- | :--- |
| Maize | $83 \%$ | $[80 \%, 85 \%]$ |
| Cassava | $35 \%$ | $[31 \%, 38 \%]$ |
| Beans | $34 \%$ | $[30 \%, 38 \%]$ |
| Mango | $33 \%$ | $[30 \%, 36 \%]$ |
| Groundnut | $22 \%$ | $[19 \%, 25 \%]$ |
| Paddy | $17 \%$ | $[14 \%, 20 \%]$ |
| Sweet potatoes | $15 \%$ | $[13 \%, 17 \%]$ |
| Sorghum | $13 \%$ | $[10 \%, 15 \%]$ |
| Cowpeas | $8 \%$ | $[7 \%, 10 \%]$ |
| Millet | $6 \%$ | $[4 \%, 8 \%]$ |
| Yams | $1 \%$ | $[0 \%, 1 \%]$ |

*Question raocode
The estimated total value of crops produced during the long rainy season in 2008 was US $\$ 1.16$ billion. Maize harvests made up about $34 \%$ of this total, followed by paddy, which accounted for $15 \%$ of the value (see Figure 9). The third highest value priority crop nationwide was beans, which made up about $6 \%$ of the total harvest value in the long rainy season. Note that $\$ 219.4$ million of the $\$ 381.8$ million generated by nonpriority crops in the long rainy season came from tobacco, cotton, and sunflower, which made up $10 \%, 5 \%$ and $4 \%$ of the total value generated respectively.

As shown in Figure 10, value generated from crops in the short rainy season was less diversified than value generated in the long rainy season. Of the estimated total, $\$ 258$ million, $28 \%$ came from paddy, $25 \%$ came from maize, and $12 \%$ came from beans. While value generated by sweet potatoes was less in the short rainy season compared to the long rainy season, $\$ 21.8$ million compared to $\$ 30.7$ million, it made up a larger share of the total value generated in the short rainy season- $8 \%$ compared to $3 \%$. Of the estimated $\$ 55.2$ million generated by non-priority crops, $\$ 26.3$ million came from cotton and $\$ 6$ million from tobacco, making up $10 \%$ and $2 \%$ of the total value generated in the short rainy season respectively (What was the estimated value of the harvested crop? How much was harvest worth in the market during harvest season?).

Figure 9: Proportion of Value Generated by BMGF Priority Crops out of all Crops Cultivated in the Long Rainy Season (USD, Total Value $=\$ 1.16$ billion, $\mathrm{N}=5335$ plots)

Question s4aq16
Figure 10: Proportion of Value Generated by BMGF Priority Crops out of all Crops Cultivated in the Short Rainy Season (USD, Total Value $=\$ 258$ million, $\mathbf{N}=1199$ plots)

[^2]
## Male- and Female-Headed Households

Male-headed households were statistically significantly more likely to grow cassava, millet, and mangoes than female-headed households (see Figure 11 for significance levels and comparison of male- and female-headed households for all crops).

Figure 11: Cultivation of Priority Crops by Male- and Female-Headed Households

*Statistically significant at the .10 level
Questions zaocode, sbmemno \& sbq2
**Statistically significant at the .05 level
***Statistically significant at the . 01 level

## Zones

Priority crop cultivation showed statistically significant variation by zone (Figure 12). Maize was most commonly cultivated by households in the Eastern and Southern Highland zones, with over $90 \%$ of households cultivating maize on at least one of their plots. By contrast, less than $10 \%$ of Zanzibar households cultivated maize; cultivation of paddy and cassava was much more common. Figure 13 shows the same data organized by zone. Maize was most commonly cultivated in every zone except for Zanzibar. The Central zone and Southern Highlands had much higher cultivation rates of maize than either paddy or cassava. The Lake and Southern zones had a more balanced mix of the three crops.

Figure 12: Zonal Cultivation of Maize, Paddy, and Cassava

Figure 13: Percent of Households Cultivating Maize, Paddy, and Cassava by Zone

[^3]Questions ₹aocode \& strataid

## Land and Labor Productivity

Land productivity was calculated as the combined harvest value of all crops per acre planted. The value included the estimated value of harvest for the long and short rainy seasons as well as the value sold of fruits and permanent crops and an estimated value of fruit and permanent crops that were not sold (What is the estimated value of the harvested crop? How much was harvest worth in the market during harvest season?). See Appendix $G$ for a more thorough explanation of the methodology used to calculate land and labor productivity figures.

These figures were calculated at the plot, household, and country level. The country level estimate is generally calculated as a single summary measure (e.g. the total value of all crops per acre) and is the estimate reported unless otherwise noted. Household and plot level productivity figures are averages across all sample observations, and hence produce a distribution of estimates. These measures are used for analysis across household level or plot level characteristics, for example, for looking at how land productivity varies by household demographics, or by plot size. See Appendix $U$ for a more thorough explanation on the differences between country, household, and plot level estimates. Appendix F contains productivity figures broken down by season at all three levels.

## Table 5: Tanzania Country Level Productivity

|  | Season | Value (USD) | Observations (number of plots used to calculate country average) |
| :---: | :---: | :---: | :---: |
| Average Land Productivity for crops only (USD/acre) | Long Rainy Season | \$45.50 | 3375 |
|  | Short Rainy Season | \$42.32 | 829 |
|  | Fruit | \$35.57 | 1459 |
|  | Permanent Crops | \$38.08 | 1336 |
|  | All Seasons | \$68.35 | 4415 |
| Average Labor Productivity | Long Rainy Season | \$1.52 | 3364 |
| (USD/day of work) | Short Rainy Season | \$1.27 | 814 |

Mean household land productivity is $\$ 95.06$ per acre across all seasons, but as shown in Figure 14, the majority of households produce less than $\$ 75$ USD per acre when the proceeds from all crops are combined. Mean household land productivity including the value of livestock by-products produced by the household is $\$ 123.76$. The median land productivity for all crops is $\$ 52.84$ per acre. Twenty-five percent of households have land productivity of less than $\$ 25$ per acre when all crops and seasons are combined and $75 \%$ of households make less than $\$ 115$ per acre. Note that the land productivity estimates do not take into account the density with which plots were planted. Therefore a one acre plot with one mango tree and one banana tree may appear to have low land productivity for fruit, while the all seasons estimate takes into account other crops that were also planted on that plot throughout the year. See the Intercropping section for more analysis on the effects of intercropping on productivity. The land productivity figures also include the entire household landholding of the household, regardless of whether some plots were left fallow.

Figure 14

Figure 15 shows the distribution of household labor productivity for crops harvested in the long rainy season. The average household produced about $\$ 1.73$ per work day in the long rainy season. The median of $\$ 0.98$ suggests that a few households produced disproportionately more per work day than the majority of households. Twenty-five percent of households produced less than $\$ 0.42$ per work day in the long rainy season. The top $25 \%$ produced more than $\$ 2.11$ per work day.

Figure 15

## Main Crop Cultivated on Plot

As shown in Figure 16, land productivity varied by the main crop planted on a particular plot. Among the BMGF priority crops, plots with paddy as the main crop produced the most value per acre in both the short and long rainy seasons. Plots with millet and sorghum as the main crop cultivated produced the lowest value per acre during the long rainy season.

Figure 16: Plot Land Productivity by Main Crop Grown on Plot

*Note, productivity figures include the value of all crops produced on the plot
**Productivity variables, s3aq5, \&o s3bq5
Labor productivity showed a similar trend (Figure 17): plots with maize, paddy, groundnuts, and beans as the main crops had the highest value per day worked, while plots with millet and sorghum were the lowest. Once again, paddy plots during the short rainy season had the highest productivity ( $\$ 4.83 /$ work day), although this was affected by the relatively small sample size (44 observations) and unequal distribution. The median labor productivity for paddy in the short rainy season was $\$ 2.25 /$ work day. However, the higher mean is not due to just a few outliers. The mean falls right around the $65^{\text {th }}$ percentile ( $\$ 4.31 /$ work day). Of the eight observations greater than $\$ 10 /$ work day, six came from the Northern Zone. Appendix I includes mean land and labor productivity figures for each of the priority crops in the long and short rainy seasons.

Figure 17: Plot Labor Productivity by Main Crop Grown on Plot

Productivity variables, s3aq5, \& s3bq5

## Male- and Female-Headed Households

Figure 18 shows productivity broken down by male- and female-headed households. Although productivity differed somewhat between male- and female-headed households, there is no statistically significant difference overall or in any individual season. ${ }^{2}$ While male-headed households had higher land productivity for long rainy season harvests and livestock, female-headed households were more productive in the short rainy season and with fruit and permanent crops.

Figure 18: Land Productivity for Male- and Female-Headed Households

Productivity variables, sbmemno, \& sbq2

[^4]Male-headed households also had slightly higher labor productivity in the long rainy season (\$1.79 compared to $\$ 1.58$ per work day), and female-headed households had slightly higher productivity in the short rainy season ( $\$ 1.39$ compared to $\$ 1.34$ per work day). Once again, these differences were not statistically significant. ${ }^{3}$ See Appendix $J$ for full comparison of productivity by male- and female-headed households and confidence intervals.

Figure 19: Labor Productivity for Male- and Female-Headed Households

Productivity variables, sbmemno, \& sbq2

[^5]
## Plot Level Decision-Making by Gender

Respondents were asked "Who decided what to plant on this plot in the long rainy season?" (s3aq6 and s3bq6 for the short rainy season). They could list up to three people, meaning that decision making could be made exclusively by males, females, or shared by people of both genders. The decision making for who decides what to plant on a particular plot could be a proxy for plot management. However, it is possible that the control over harvest may be distributed differently than the decision-making about planting. Productivity for all crops at the plot level was highest for plots with shared decision making (\$118.19/acre) and lowest for plots with female decision making ( $\$ 105.43 /$ acre $)$, with plots with male decision-makers in the middle ( $\$ 111.49$ /acre). However, the variation was not statistically significant. ${ }^{4}$ As shown in Figure 20, there was statistically significant variation in labor productivity by the gender of the plot decision-maker during the long rainy season. Plots where only females decided what to plant fared the poorest, with $\$ 1.53 /$ work day, while plots with male decision-makers had the highest labor productivity - $\$ 1.93 /$ work day. In the short rainy season plots with shared decision making had the lowest productivity, although the variation was not statistically significant.
Figure 20: Labor Productivity by Gender of Decision-Maker

Productivity variables, sbmemno, sbq2, s3aq6, os s3bq6
See Appendix $K$ for a comparison of land and labor productivity by gender of decision-maker for all seasons.

[^6]
## Zones

Productivity differed by zone, due in part to differing natural conditions and mix of agricultural activities in each zone. Figure 21 shows the average annual value produced by households in each zone distinguished by the types of agricultural activities that produced that value.

Figure 21: Average Household Value Produced from Agricultural Activities by Zone and Season/Type of Product

The survey did not provide information on land dedicated to livestock husbandry, so the livestock byproducts may falsely elevate land productivity if respondents did not graze/care for their animals on the plots that they reported cultivating and/or owning in the agricultural module. Figure 22 shows value produced by zone not including livestock by-products. Note that the Northern zone produces similar value to the other zones when livestock by-products are not included in the value produced.

Figure 22. Average Household Value Produced from Agricultural Activities by Zone and Season/Type of Crop (excluding livestock by-products)

Figure 23 shows the total household land productivity from all crops and livestock, broken down by zone. Note that although the Northern zone appears to be much more productive, much of this may be due to the large value obtained from livestock by-products as shown in Figure 21. Figure 24 shows labor productivity by zone for the long rainy season.

Figure 23: Total Household Land Productivity from All Crops \& Livestock by Zone

Figure 24: Long Rainy Season Household Labor Productivity by Zone

## Farm Characteristics and Productivity

As shown in Figure 25, household land productivity is negatively correlated with landholding size, ${ }^{5}$ meaning higher productivity is associated with smaller landholding size, although the correlation is weak. ${ }^{6}$

Figure 25

*Note: scatter plot is of un-weighted data and therefore is not nationally representative

[^7]
## Crop Sales

The majority of farmers growing priority crops did not sell any of their harvest, with the exception of the $52 \%$ of paddy growers in the long rainy season (see Figure 20). The crops that were least often sold in the long rainy season were sorghum and cassava; $15 \%$ and $16 \%$ of households that grew these crops sold them, respectively. Between $20 \%$ and $30 \%$ of households that cultivated sweet potatoes, cowpeas, and maize in the long rainy season sold some of these crops. Millet and groundnuts were most commonly sold after paddy, with more than $40 \%$ of households selling some of what they produced in the long rainy season. Generally, a greater proportion of households sold their crops in the long rainy season than in the short rainy season (Did you sell any of the [CROP] produced in the long rainy season 2008/ last completed short rainy season?). Appendix $N$ includes the means along with confidence intervals and number of observations for the proportion of households cultivating each of the priority crops that sold them in the long and short rainy season as well as permanent crops and fruit.

Figure 26: Estimated Proportion of Households Growing Priority Crops that Sold Them

$\dagger$ Insufficient observations to obtain reliable proportions for
Questions zaocode, s5aq1 \& s5aq2
sorghum and millet in the short rainy season and yams in the
long and short rainy seasons

Figure 27 shows the mean and median prices received per kilogram of crops sold in the long rainy season. The means and medians are very similar for maize, paddy, and cassava, indicating that the prices are somewhat evenly distributed. Beans were the most valuable crop per kilogram; respondents received an average of $\$ 0.50$ per kilogram (median $=\$ 0.42$ ) in the long rainy season. Cassava was the least valuable crop per kilogram, with an average price of $\$ 0.15$ per kilogram (median $=\$ 0.13$ ) (What was the quantity sold? What was the total value of sales?). ${ }^{7}$ Appendix $O$ includes the mean and median prices for all priority crops in the long and short rainy seasons and for permanent crops and fruit with confidence intervals.

Figure 27: Mean and Median Prices Received per Kilogram of Crops Sold - Long Rainy Season

*Permanent crop observations
Questions zaocode, s5aq2 \& s5aq3
$\dagger$ Insufficient observations to obtain a reliable mean for yams

[^8]The distributions of amount received per kilogram of maize, paddy, and cassava were fairly symmetrical (see Figure 28, Figure 29, and Figure 30). As shown in Figure 28, most prices received for maize per kilogram were clustered around the mean and median ( $\$ 0.19$ ). Over $90 \%$ of the observations were between $\$ 0.09$ and $\$ 0.34$ per kilogram. Variations in prices may reflect local supply and demand differences due to the location of the seller, or due to the time of sale.

Figure 28

## Questions raocode, s5aq2 \&o s5aq3

As shown in Figure 29, the price received for paddy during the long rainy season was also fairly symmetrical, with a peak at just above $\$ 0.30$, and another slightly above $\$ 0.40$ per kilogram. The mean price received was $\$ 0.34$ per kilogram, and the median was $\$ 0.33$ per kilogram. Twenty-five percent of paddy growers who sold their crops received $\$ 0.25$ per kilogram or less, and $25 \%$ received more than $\$ 0.41$ per kilogram.

Figure 29

Figure 30 illustrates that the prices received for cassava were generally lower than those received for maize and paddy, and the distribution was somewhat flatter, which may be due to sellers able to take advantage of multiple peak times for selling the crop over the year. The mean amount received per kilogram was $\$ 0.15$, and the median was $\$ 0.13$. Twenty-five percent of households received less than $\$ 0.07$ per kilogram, and $10 \%$ of households received $\$ 0.27$ per kilogram or more.

Figure 30

Questions zaocode, s5aq2 \&o s5aq3

Figure 31 shows the mean and median values of crops sold by household. Most of the mean values were more than twice as much as the medians, indicating that a small group of households earned disproportionately more from sales of each of these crops. Since the price per kilogram was less varied (see Figure 27), it suggests that the disparity between the mean and median value of crops sold by households is driven by large differences in the quantities sold, rather than in the prices received. The mean and median values for each of the priority crops in the long and short rainy seasons and for permanent crops and fruit with confidence intervals and numbers of observations can be found in Appendix P.

Figure 31: Mean and Median Value of Crop Sold in the Long Rainy Season of Households Growing Each Priority Crop

Questions zaocode \& s saq3
The distributions of total value of sales for maize and paddy in the long rainy season and cassava permanent crop observations are shown in Figure 32, Figure 33, and Figure 34. While the mean value of maize sales per household was $\$ 89.09$ in the long rainy season, the median was $\$ 40.04$, and $40 \%$ of households earned $\$ 30$ or less. Twenty-five percent of households received $\$ 100$ or more for maize sales in the long rainy season.

Figure 32

Questions zacoode ér 5 aq3
As shown in Figure 33, the distribution of household value of sales for paddy in the long rainy season follows a similar pattern to that of maize. The mean value of sales per household was $\$ 209.77$, and the median was much lower: $\$ 83.42$. Twenty-five percent of households earned less than $\$ 30$ from paddy sales, and $25 \%$ earned more than $\$ 233$.

Figure 33

Questions zaocode é s5aq3

As shown in Figure 34, households generally received less value from sales for cassava than for either maize or paddy, with most households earning less than $\$ 18$. The mean value of $\$ 65.53$ was at about the $82^{\text {nd }}$ percentile, meaning that only $18 \%$ of households earned this much or more. The majority of households made less than $\$ 18$ from sales of cassava, and $25 \%$ of households made less than $\$ 7$.

Questions zaocode of s5aq3

## Male- and Female-Headed Households

With the exception of households that grew sweet potatoes, male-headed households that grew each of the priority crops during the long rainy season were more likely to sell those crops than female-headed households (for crops with sufficient observations, see Figure 35). However, maize was the only priority crop for which the difference was statistically significant. $31 \%$ of male-headed households that grew maize in the long rainy season sold some of their crop ( 305 out of 1,010 observations), while only $21 \%$ of female-headed households did so ( 69 out of 327 observations). Appendix $Q$ includes a comparison of the proportion of households selling each priority crops in the long rainy season by gender of household head with confidence intervals and levels of statistical significance.

Figure 35: Proportion of Households that Sold Crops by Gender of Household Head

* Statistically significant at the .10 level
**Statistically significant at the .05 level
***Statistically significant at the . 01 level
$\dagger$ Insufficient observations to calculate reliable estimates for millet, yams, and cowpeas
Questions sbmemno, sbq2 \& s5aq1

In addition to being more likely to sell their crops, male-headed households also earned more, on average, from sales of their maize crops in the long rainy season than did female-headed households (see Figure 36 ). Male-headed households made an average of $\$ 96.73$ from maize sales in the long rainy season; female-headed households made an average of $\$ 55.64$. This difference was statistically significant at the $99 \%$ confidence level. Female-headed households also earned less from paddy sales, an average of $\$ 111.99$, compared to the mean of $\$ 238.92$ earned by male-headed households in the long rainy season (see Figure 37), a difference significant at the $95 \%$ confidence level.

Figure 36: Mean Value of Maize Sales by Gender of Household Head Long Rainy Season

Figure 37: Mean Value of Paddy Sales by Gender of Household Head Long Rainy Season

**Difference is statistically significant at the .05 level Questions sbmemno, sbq2 \& s5aq3

## Zones

As shown in Figure 38, the proportion of households who sold some of their harvest varied by zone. The Southern Highlands had the highest proportion of households that sold each of the three crops shown (maize, paddy, and cassava; $43 \%, 88 \%$ and $37 \%$ of households sold these crops respectively). Households in the Eastern zone were less likely to sell their crops; only $17 \%$ sold any of their maize harvest, just over $40 \%$ sold paddy, and $28 \%$ sold cassava. Notably, although Zanzibar has the highest proportion of households that grow paddy ( $51 \%$ ), 0 out of 130 households reported selling any of their harvest. Full results for proportion of households selling each priority crop by zone with confidence intervals and numbers of observations can be found in Appendix R.

## Yield Measures

Figure 39 shows country yields for area harvested for each priority crop for the short and long rainy seasons compared to commonly used yield numbers from the Food and Agriculture Organization (FAO). ${ }^{8}$ As evidenced in the table, the calculations obtained through LSMS data were consistently below FAO yield estimates for the same year. While the FAO estimates are annual, ${ }^{9}$ the LSMS data separates crop information by season. Short and long rainy season crops are typically harvested at the end of each season, while permanent crops, for example cassava, may be left in the ground for up to several years (What was the area barvested in the long rainy season 2008/ last short rainy season? What was the quantity barvested?).

Figure 39: Priority Crop Country Yield Estimates for Area Harvested by Season

* The FAO 2008 yield estimate for cassava is $2,605 \mathrm{~kg} /$ acre.

Questions s4aq8, s4bq8, s4aq15 \& s4bq15
There were also 609 observations of plots with cassava yields recorded
as a permanent crop. The country yield for these plots was $183 \mathrm{~kg} /$ acre, assuming the entire plot was planted with cassava.
$\dagger$ Insufficient observations to calculate reliable yield estimates for sorghum and millet in the short rainy season and for yams in the long and short rainy seasons.

[^9]There were insufficient observations (fewer than 30 ) to calculate reliable yield estimates for sorghum and millet in the short rainy season and for yams in both the long and short rainy seasons. The yield estimates for these crops are included in Appendix $S$, along with yield estimates at the plot, household and country level for all ten priority crops and mangos. Note that the area harvested question in the survey does ask respondents to specify the density of the area planted. Respondents could have planted less of a crop on a plot due to intercropping and reported the same area harvested as someone who did not intercrop. For more information on the frequency of intercropping and its effect on yields and productivity see the Intercropping section.

Table 6 shows six different yield estimates for maize that can be calculated using LSMS data as compared to FAO estimates from the same year (2008). The bolded estimate was calculated using country-level estimates of crop output per area harvested, the methodology most similar to the FAO.

Area barvested and area planted 10
Yield calculations from the LSMS-ISA are possible using the area harvested or the area planted in the denominator. Area harvested is a more common measure, though it hides crop losses during the season or during harvest. The area planted includes plots where no harvest took place due to destruction. It also includes the portions of plots that were planted but not harvested due to drought, rains, fire, insects, animals, crop theft, diseases and community problems, lack of casual labor, and other reasons. See Appendix $T$ for a fuller description of the differences between the area planted and area harvested variables and the Pre- and Post-Harvest Losses section for information on the magnitude and reasons for pre-harvest losses.

Table 6: Yield Comparison for Maize

| Maize, Long Rainy Season | Mean Yield (kg/acre) | Confidence Interval | $\text { FAO: } 505$ <br> Observations |
| :---: | :---: | :---: | :---: |
|  |  |  |  |
| Country Harvested | 323 |  | 1811 |
| Planted | 225 |  | 1888 |
| Household Harvested | 367 | [ 345,390$]$ | 1284 |
| Planted | 293 | [272, 313] | 1324 |
| Plot Harvested | 372 | [347, 396] | 1811 |
| Planted | 304 | [283, 326] | 1888 |
| Maize, Short Rainy Season |  |  |  |
| Country Harvested | 242 |  | 396 |
| Planted | 142 |  | 440 |
| Household Harvested | 284 | [240, 328] | 311 |
| Planted | 204 | [166, 242] | 339 |
| Plot Harvested | 273 | [234, 313] | 396 |
| Planted | 197 | [165, 229] | 440 |

[^10]The country level yield estimate is simply the sum, over all plot observations, of the quantity produced (kilograms harvested) divided by the area harvested or planted. There are no standard error estimates for country level yields. Appendix $S$ includes all six yield calculations for each priority crop.

As shown in Figure 40, Figure 41, and Figure 42, the distribution of household yields varies across crops.

**Yield calculated using area harvested

## Household Yield Gap

As shown in Figure 43, the median household yields for each priority crop were generally much lower than the $90^{\text {th }}$ percentile, indicating that many farmers could potentially achieve higher yields. Paddy yields in the long rainy season had the largest disparity between the median and the $90^{\text {th }}$, with the most productive households producing $500 \%$ more kilograms per acre than the median households. Sweet potatoes had the smallest yield gap; the $90^{\text {th }}$ percentile produced $48 \%$ more kilograms per acre than the median household.

Figure 43: Comparison of Median Household Yields to $90^{\text {th }}$ Percentile - Long Rainy Season

$\dagger$ Insufficient observations to calculate reliable yield estimates for yams

## Complications with Cassava Observations:

Cassava generally is not planted and harvested within one rainy season, so it was supposed to be listed as a permanent crop by the survey enumerators. However, some enumerators listed cassava as a crop in the long and short rainy seasons and subsequently asked the questions associated with those seasons to survey respondents. The questions asked about crops in the long and short rainy seasons differed from the questions asked about fruit and permanent crops, so all of the cassava observations could not be combined into one dataset. For example, fruit and permanent crop observations do not have data on the portion of the plot planted with each crop, on the area harvested, or on improved variety seeds. Therefore, yield calculations for cassava as a permanent crop differed from the calculations of cassava and other crops during the long and short rainy seasons. Generally when comparing across crops this report uses long rainy season observations of cassava.

However, the data collection errors were not distributed evenly, which calls into question whether yield calculations for cassava are truly nationally representative. The vast majority of long rainy season yield observations for cassava were located in Zanzibar, followed by the Southern zone (179 and 38 plot yield observations respectively out of 221 total observations for area harvested yields). In the short rainy season, 43 out of 45 plot yield observations were located in Zanzibar. The permanent crop observations were more evenly distributed among zones.

There were several other issues with the data that affected the yield estimates. For a more detailed account of these issues and how they may affected the yield estimates, see Appendix MM.

## Male- and Female-Headed Households

Male-headed households produced higher yields than female-headed households for all crops except paddy in the long rainy season (see Figure 44). However, in most cases the magnitude of difference was small and not statistically significant. While average cassava yields reported in the long rainy season were statistically significantly higher for male-headed households ( $822 \mathrm{~kg} /$ acre compared to $609 \mathrm{~kg} /$ acre ), average cassava yields reported as permanent crops (with more observations than for the long rainy season) were higher for female-headed households ( $331 \mathrm{~kg} /$ acre compared to $441 \mathrm{~kg} /$ acre).

Figure 44: Comparison of Long Rainy Season Plot Yields by Gender of Household Head (area harvested)

[^11]
## Plot Level Decision-Making by Gender

Respondents reported on who decided what to plant on each plot in the long and short rainy seasons. They could list up to three people, meaning that decision making could be made exclusively by males, females, or shared by people of both genders. With the exception of sorghum and cowpeas, yields during the long rainy season were highest on plots where decision-making was shared between males and females (see Figure 45). Plots that had exclusively female decision-makers had the lowest yields for every long rainy season crop analyzed, with the exception of millet where yields were slightly lower for plots with exclusive male decisionmaking. However, the magnitude in difference in yields by gender of decision-makers was generally not large and the differences were not statistically significant for most of the priority crops. This simple relationship between the gender of the decision-maker and yield also does not control for other potentially important variables such as plot size, quality, and input use. In addition, other aspects of plot decision making, such as control over harvest decisions, may also have important impacts on yields that are not captured by this question. See Appendix $V$ for a full comparison for all crops in each season with test results for statistical significance (Who decided what to plant on this plot in the long rainy season?).

Figure 45: Comparison of Long Rainy Season Plot Yields by Gender of Decision-Maker (area harvested)

[^12]Yield variables, sbmemno, sbq2, s3aq6, \&os $3 b q 6$

## Zones

As shown in Figure 46, yields vary by zone. The Southern Highlands, for example had the highest average yields of any zone with sufficient observations for maize and paddy in the long rainy season (510 and 922 $\mathrm{kg} /$ acre respectively). While the median yields were generally lower than the means, the zonal variation followed the same pattern. The Southern Highlands had the highest median yields for both maize and paddy ( 396 and $750 \mathrm{~kg} /$ acre respectively). While Zanzibar had the lowest average paddy yield, $316 \mathrm{~kg} / \mathrm{acre}$, the average household cassava yields of $674 \mathrm{~kg} /$ acre in Zanzibar exceeded those of any other zone. Zanzibar also had the lowest median paddy yield ( $224 \mathrm{~kg} /$ acre) and the highest median cassava yield ( $420 \mathrm{~kg} / \mathrm{acre}$ ). The Lake zone had lower average yields for maize and cassava and several other priority crops. See Appendix $X$ for a full report of average long and short rainy season household yields by zone and Section B - Median Farmer Profile for the median yields by zone.

Figure 46: Average Household Yield by Zone for Maize and Paddy in the Long Rainy Season and Cassava Permanent Crop Observations

*Note: Yield values calculated using the area harvested
$\dagger$ Insufficient observations to calculate reliable average yields for maize in Zanzibar; paddy in the Central, Lake and Northern zones; and Cassava in the Central zone and the Southern Highlands

## Farm Characteristics

As shown in Figure 47, paddy yields were higher for households that own more plots, though maize and cassava do not show a clear relationship between the number of plots owned by a particular household and average yield.

Figure 47: Average Yields by Number of Plots

Yield variables, st2q1, st2q2, st2q3, st2q4, s2aq4, \& s2bq4

As shown in Figure 48, smaller plots tended to produce higher yields of maize in the long rainy season. The correlation was weak, but was statistically significant at the $99 \%$ confidence level. ${ }^{11}$ Paddy and cassava yields were also negatively correlated with plot size and these correlations were statistically significant ${ }^{12}$ (see Figure 49 and Figure 50). See Appendix Y for correlation coefficients of all priority crops with plot size.

[^13]Figure 48

*Note: scatter plot is of un-weighted data and therefore is not nationally representative
Figure 49

[^14]Figure 50

[^15]
## Intercropping

An estimated $63 \%$ of plots reported in the LSMS-ISA were intercropped. Intercropping varied by season and type of crop, with the lowest proportion of intercropping occurring during the long rainy season and fruit the most likely to be intercropped (see Table 7), as measured by the number of plots that contain a fruit tree and additional crop - independent of the quantity of either crop (W as cultivation intercropped?).

Table 7: Estimated Proportion of Plots Intercropped by Season

| Season | Estimated <br> proportion | 95\% C.I. | Observations |
| :--- | :--- | :---: | :--- |
| Fruit | $82 \%$ | $[79 \%, 86 \%]$ | 1650 |
| Permanent Crops | $78 \%$ | $[75 \%, 82 \%]$ | 1788 |
| All Short Rainy <br> Season Plots | $67 \%$ | $[62 \%, 72 \%]$ | 786 |
| All Long Rainy <br> Season Plots | $54 \%$ | $[51 \%, 57 \%]$ | 3355 |
| All Crops/Seasons | $\mathbf{6 3 \%}$ | $[\mathbf{6 0 \%} \%, \mathbf{6 5 \%} \%$ | $\mathbf{4 5 6 1}$ |

* Questions s4aq6, s4bq6, s6aq5 \&o s6bq5

As evident in Figure 51, intercropping varied substantially by crop planted. Legumes were most commonly intercropped, and paddy was intercropped much less than any other priority crops. Appendix $Z$ includes proportion of plots intercropped by crop for the long and short rainy seasons, permanent crops and fruit.

Figure 51: Estimated Proportion of Plots Intercropped by Crop Planted

$\dagger$ Insufficient observations to calculate reliable yield estimates for sorghum and millet in the short rainy season and for yams in the long and short rainy seasons.

As shown in Figure 52, the majority of plots were intercropped to mitigate the risk of crop failure. Full results and confidence intervals for reasons for intercropping are in Appendix Z. (Reason for intercropping options: substitute if either crop fails, more fertile for the soil, other)

Figure 52: Reasons for Intercropping Plots

*N=2,733 plots; Includes long and short rainy season and fruit $\quad * *$ Questions s4aq7, s4bq7, s6aq6 \& s6bq6 and permanent crop observations

## Intercropping and Yields

With the exception of sweet potatoes, each priority crop had statistically significant lower yields in intercropped plots than in crops that were not intercropped during the long rainy season (see Figure 53), though this result does not account for difference in planting density on intercropped and monocropped plots. Paddy had the largest discrepancy in yields between intercropped and non-intercropped fields, which may explain in part why it is so infrequently intercropped compared to other priority crops. Maize was the only crop in the short rainy season with enough observations to reliably compare yields of intercropped and non-intercropped plots. Yields for intercropped plots were $265 \mathrm{~kg} /$ acre, compared to $298 \mathrm{~kg} /$ acre for nonintercropped plots. However, this difference was not statistically significant. For a comparison of yields for all priority crops in both rainy seasons see Appendix $A A$.

Figure 53: Long Rainy Season Plot Yields for Crops that were Intercropped Compared to NonIntercropped Plots

* Statistically significant at the .10 level
**Statistically significant at the .05 level
***Statistically significant at the .01 level
$\dagger$ Insufficient observations to calculate reliable yield estimates for yams and conpeas

## Intercropping and Land and Labor Productivity

As seen in Figure 54, when we take into account the value from all crops harvested on a plot, intercropped plots with main crops of maize, sorghum, and sweet potatoes all produced more value per acre than nonintercropped plots with these main crops. However, none of these differences are statistically significant. Non-intercropped plots with main crops of paddy, beans, millet, groundnut, and cassava produced more value per acre than intercropped plots with these main crops. The difference was only statistically significant for plots with paddy and cassava as the main crop.

Figure 54: Long Rainy Season Land Productivity for Plots that were Intercropped Compared to Non-Intercropped Plots

* Statistically significant at the .10 level
**Statistically significant at the .05 level
***Statistically significant at the .01 level
$\dagger$ Insufficient observations to calculate reliable yield estimates for yams and conpeas

However, although non-intercropped plots with cassava as the main crop had statistically significantly higher land productivity, the labor productivity was actually slightly lower for these plots, though this difference was not statistically significant (see Figure 55). Paddy and groundnuts were the only two main crops that had higher labor productivity for non-intercropped plots than for non-intercropped plots. All other priority crops had higher labor productivity on intercropped plots, suggesting that intercropping may create some labor efficiencies. As shown in Figure 54 and Figure 55, most of the productivity differences between intercropped and non-intercropped plots were inconsistent by crop and not statistically significant. Intercropping is a very complex topic and may warrant further research and analysis in order to more fully understand its effects on productivity. Appendix $B B$ has the full results from the bivariate analysis of productivity and intercropping.

Figure 55: Long Rainy Season Labor Productivity for Plots that were Intercropped Compared to Non-Intercropped Plots

* Statistically significant at the .10 level
**Statistically significant at the .05 level
***Statistically significant at the . 01 level
$\dagger$ Insufficient observations to calculate reliable yield estimates for yams and conpeas

## Pre- and Post-Harvest Losses

## Pre-Harvest Losses

About a third to a half of priority crop plots lost a portion of the area planted to pre-harvest losses. Generally, pre-harvest losses were more common in the short rainy season than in the long rainy season (see Figure 50). As shown in Figure 57, the causes of pre-harvest losses varied by crop. Birds were the most common cause of pre-harvest losses for paddy, while maize and cassava experienced the highest proportion of losses due to animals. Appendix CC has summary statistics for the proportion of all priority crops that have pre-harvest losses in the long and short rainy seasons and permanent crops and fruit. Appendix $D D$ includes the causes of pre-harvest losses for priority crops in the long rainy season and permanent crops and fruit (Were there any losses of crops before the harvest? What was the cause of these losses?).

Figure 56: Estimated Proportion of Plots with Pre-Harvest Losses by Crop Harvested

Questions staq17, s4bq17 s6aq9 \& s6bq9

Figure 57: Causes of Pre-Harvest Losses for Maize, Paddy, and Cassava by Plot

Questions s4aq18, s4bq18, s6aq10 \& s6bq10

## Plots with Area Harvested Less than Area Planted

Figure 58 shows the estimated proportion of priority crop plots that had a smaller area harvested than the area planted in the long and short rainy seasons. With the exception of cassava, a higher proportion of plots had a smaller area harvested than planted in the short rainy season than in the long rainy season. Millet, cowpeas, and beans had the highest proportion of plots with a smaller area harvested in the long rainy season-40\%, $38 \%$ and $33 \%$ respectively. Paddy and sweet potatoes had the lowest proportion of plots affected in the long rainy season. In the short rainy season, over $45 \%$ of maize, cowpeas, and groundnut plots had a smaller area harvested than the area planted, and over $50 \%$ of bean plots were not fully harvested (W as area barvested less than area planted?). See Appendix EE for full results and confidence intervals.

Figure 58: Estimated Proportion of Priority Crop Plots with an Area Harvested less than the Area Planted

$\dagger$ Insufficient observations to calculate reliable estimates for
Questions zaocode s4aq9 \& s4bq9
sorghum and millet in the short rainy season and for yams in the
long and short rainy seasons.

Figure 59, Figure 60 and Figure 61 show the reasons why the area harvested was less than the area planted for maize, paddy, and cassava plots in the long rainy season. Drought was the most prominent reason for both maize and paddy plots during the long rainy season. Fifteen percent of plots were not fully harvested due to this reason for both crops. Drought was less of a problem for cassava, accounting for smaller areas harvested on only $3 \%$ of plots. Insects were a relatively larger problem for cassava; $16 \%$ of cassava plots in the long rainy season had a smaller area harvested than planted due to insects (What was the reason it was less than the area planted? Options: drought; effects of rains, fire, insects, animals, crop theft, diseases and community problems, lack of casual labor or other). See Appendix FF for reasons for smaller areas harvested for all priority crops in the long rainy season.

Questions zaocode s3aq10

## Entire Plots not Harvested due to Destruction

Several respondents indicated that their entire harvest was lost due to destruction (see Figure 62). Losses of the entire harvest were generally higher in the short rainy season, with respondents indicating losses of over $5 \%$ of plots for five different priority crops (cowpeas, cassava, beans, maize, and groundnuts). The highest reported losses were of cassava in the short rainy season, where an estimated $20.9 \%$ of plots were not harvested due to destruction ( 10 out of 55 observations). In the long rainy season, farmers reported losing harvests from less than $1 \%$ of plots (millet and sweet potatoes) to over $5 \%$ for cowpeas and cassava (11 out of 140 observations and 15 out of 207 observations respectively). Appendix $G G$ shows estimated proportions and confidence intervals for all priority crops that were not harvested due to destruction in the short and long rainy seasons (Did you barvest any [CROP] on this plot in the long-rainy [or short-rainy] season 2008? Why didn't you barvest any [CROP] on this plot? ${ }^{13}$ ).

[^16]Figure 62: Estimated Proportion of Plots that Lost Entire Harvest of Priority Crops to Destruction

## Questions s4aq2 \& s4bq2

## Portions of Plots not Planted due to Constraints

A substantial portion of farmers did not plant an entire plot due to a constraint—drought, lack of tools/equipment, lack of seeds, floods, lack of loans, or lack of agricultural equipment. ${ }^{14}$ In the long rainy season, over $25 \%$ of bean plots were not fully planted due to some type of constraint (see Figure 63). Constraints to maize, paddy, and cassava affected the smallest proportion of plots; less than $15 \%$ of plots were not fully planted with these crops due to constraints (Was [CROP] planted in entire area of plot? Why didn't you plant the entire plot with [CROP]?).

[^17]Figure 63: Estimated Proportion of Plots not Entirely Planted due to Constraints by Crop

## Questions staq3 \& s4bq3

As shown in Figure 64, Figure 65, and Figure 66, each crop faced different constraints, although lack of access to agricultural tools and equipment was the most prevalent constraint for maize, paddy, and cassava. This finding is not surprising given the low proportion of farming households that own farm implements as shown earlier in Table 1. While lack of seeds was not a large constraint for maize or paddy (affecting $1 \%$ and $2 \%$ of plots respectively), it was a much larger problem for beans- $9 \%$ of plots were not fully planted with beans due to a lack of seeds.

Questions zaocode ér staq5

## Post-Harvest Losses

Post-harvest losses by households varied by crop; from about $5 \%$ of households reporting post-harvest losses of beans to $15 \%$ of households reporting losses of paddy in the long rainy season (see Figure 67). For some crops, such as paddy and beans, the proportion of plots with reported post-harvest losses was greater in the short rainy season than the long rainy season. However, for all other priority crops with sufficient observations, a higher percentage of households reported post-harvest losses in the long rainy season. Rodents and pests were the most common causes of post-harvest losses for maize and paddy during the long rainy season and cassava permanent crop observations (Figure 68). However, this pattern did not hold for most other crops (see Appendix JJ and Appendix KK for full summary statistics by crop and season) (Was any portion of the production lost post-harvest to rotting, insects, rodents, theft, etc.? Reason for loss). On average, maize farmers in the long rainy season who suffered post-harvest losses reported losing about $18 \%$ of their harvest, and paddy farmers reported losing about $15 \%$ in response to the question (Out of 10 units of [CROP], how many were lost?). Appendix $L L$ includes the percentage lost by each crop for all priority crops.

## Appendix G Methodology for Productivity

The productivity estimations use the value of production from the long rainy season, short rainy season, fruit, permanent crops, and livestock by-products.

The value of long and short rainy season productivity was calculated by summing the estimated value of harvest for each crop on a given plot (What is the estimated value of the harvested crop? How much was harvest worth in the market during the harvest season?). If the respondent had not finished the harvest, the value of the crop not yet harvested was projected by assigning the same value/kilogram to the amount left to be harvested (What fraction of the crop remains to be harvested in this period?).

Respondents were not asked the estimated value of production for fruit and permanent crops. The value of these crops was calculated by adding the value of the crop that was sold to an estimated value of crops not sold that was calculated using a shadow price. For observations that did sell some of a crop, the price $/ \mathrm{kg}$ that they received for what they sold was applied to the remaining amount that they did not sell. Many producers, however, did not report selling any of the fruit and permanent crops that they produced. For these observations, the shadow price applied was the country-wide average price received for the crop grown (What was the total amount of [FRUIT/CROP] barvested in the past 12 months? What was the total quantity sold of the quantity collected? What was the total value of [FRUIT/ CROP] sold?).

For both rainy seasons, fruit, and permanent crops, values of zero were treated as missing unless some type of destruction was cited as a reason for producing no value (For long and short rainy seasons: Why didn't you barvest any [CROP] on this plot?). Responses of "destruction" were counted as values of zero, while all other options were counted as missing (such as "not mine to harvest" and "still in plot") (Fruit and permanent crops: What was the cause of these losses?). Responses of "birds, animals, insects, and diseases" were counted as values of zero and "theft and other" were counted as missing.

Livestock by-products included traditional and improved cow milk and eggs, honey, skins and hides, and other byproducts. The value of these products was calculated by multiplying the average quantity produced per month by the number of months that the household produced that by-product and applying prices and shadow prices using the same methodology as was used for fruit and permanent crops (During the last 12 months, for how many months did your household produce any [PRODUCT]? During these months, what was the average quantity of [PRODUCT] produced per month? How much of the [PRODUCT] produced did you sell in the last 12 months? What was the total value of sales of [PRODUCT] in the last 12 months?).

Land productivity was calculated for the long rainy season, short rainy season, fruit and permanent crops individually by dividing the value from that season/type of crop by the plot size/household landholding/country area cultivated depending on the level. See Appendix $T$ for an explanation of the differences between plot, household, and country level calculations. Note that at the household level if a respondent cultivated on any one of his/her plots during a particular season, the entire household landholding was factored into the land productivity figure, regardless of whether or not that household cultivated on all plots. The productivity figure for all crops was calculated by adding up the value from the long and short rainy seasons, fruit, and permanent crops, and dividing by the number of acres at each level (plot, household, and country). The value of livestock by-products was added in for a final estimate of productivity at the household level. The survey did not ask about the land used by livestock, so this productivity estimation assumes that households use exclusively their own plots for livestock production, as opposed to any communal grazing land (Please list all plots anyone in your household cultivated during the 2008 long rainy season/short rainy season - Area, Acres).

Labor productivity was calculated for each season by dividing the value produced by long and short rainy season crops by the days of household labor and hired labor dedicated to land preparation and planting, weeding, and harvesting in each season. The survey did not include questions about labor for fruit and permanent crop cultivation or for animal husbandry. Therefore this report only includes labor productivity estimations for crops grown in the long and short rainy seasons (During the long rainy season 2008/ last completed short rainy season bow many days did [NAME] spend on the following activities on this plot - land preparation and planting, weeding, barvesting? During the long rainy season 2008/ last completed short rainy season how many days did your household have bired labor for this plot for [...]?).

## Appendix H Productivity Data Issues

| Issue | Description | Number of observations affected | Direction of effect | Magnitude of effect |
| :---: | :---: | :---: | :---: | :---: |
| Fruits and Permanent crops without household prices | Respondents are only asked for the value of fruit and permanent crops that were sold, and not for the value of these crops that were harvested. The value of the harvest is calculated by multiplying the price $/ \mathrm{kg}$ of the crop that was sold by the total harvested amount (to account for sold and consumed product). For households that did not report any sales, the mean price $/ \mathrm{kg}$ reported by households that did sell a given crop was used. | Shadow prices created for $\mathbf{3 , 9 7 8}$ out of 5,696 fruit/permanent crop observations (69.8\%) | Unknown, but most likely overestimates productivity because crops that are not sold may have lower values than crops sold | Unknown; overall effect could be large due to the high percentage of observations with shadow prices. Some shadow prices were created from a very small number of observations. |
| Fruits and Permanent crops without prices in entire data set | There were a few fruit and permanent crops that were not reported as sold by any of the households who grew those crops. These crops were excluded from productivity calculations as there was no way to estimate their value. | Total of $\mathbf{5 4}$ out of 5,696 fruit permanent crop observations (0.9\%) <br> Crops include: <br> Malay apple, <br> Rubber, <br> Wattle, <br> Tamarin, <br> Grapefruit, <br> Grapes, <br> God fruit, <br> Mitobo, <br> Pomegranate, <br> Tungamaa, Firewood/fodder, Medicinal plant, Fence tree, or 999 (other) | Underestimates productivity because no value is attributed to these crops | Unknown; overall effect is small due to the limited number of observations |
| Inaccurate responses/recall | Many of the questions require respondents to give information that they may not know precisely or | All responses subject to | Unknown; in the case of land size, | Unknown |

|  | accurately remember (e.g. kilograms of fruit harvested in the past 12 months or total estimated value of maize harvest in the long rainy season). | inaccuracies | overestimates <br> productivity <br> because respondents tended to report smaller plots than those that were measured |  |
| :---: | :---: | :---: | :---: | :---: |
| Recall issues with days worked | Respondents were asked to list the different people that worked on a number of agricultural activities during the long and short rainy seasons and the number of days that they spent on that activity during the season. There were a number of responses of 99 , indicating that the respondent did not remember the number of days worked. ${ }^{15}$ Observations for which the respondent answered 99 for all labor sources were not included in this analysis. However, if the respondent reported work days for some labor sources and could not recall others, the observations were included and only the labor sources with 99 responses were treated as missing, not the entire household observation. | Long rainy season: 297 out of 3364 plot observations (8.8\%) <br> Short rainy season: 109 out of 814 plot observations (13.4\%) | Should overestimate labor productivity due to unreported labor excluded from denominator; however, when observations with 99's were excluded from these summary statistics, labor productivity actually increased | Mean long rainy season plot labor productivity with all observations: 2174 TSH/day of labor <br> Mean long rainy season plot labor productivity excluding observations with 99's: 2184 TSH/day of labor <br> Mean short rainy season plot labor productivity with all observations: 1712 TSH/day of labor <br> Mean short rainy season plot labor productivity excluding observations with 99's: 1743 TSH/day of labor |

[^18] indicate that 99 should be used when respondents cannot remember the answer for several other questions, so we infer that 99 has the same meaning for this question.

## Appendix I Plot Land and Labor Productivity by Primary Crop Planted on Plot

| Long Rainy Season Land Productivity by Primary Crop Planted on Plot |  |  |  |
| :--- | :--- | :--- | :--- |
|  | Mean (USD/Acre) | $95 \%$ C.I. | Observations |
| Yams | $\$ 156.54$ | $[\$ 41.48, \$ 271.59]$ | 15 |
| Paddy | $\$ 141.36$ | $[\$ 121.29, \$ 161.43]$ | 460 |
| Maize | $\$ 63.47$ | $[\$ 59.01, \$ 67.94]$ | 1547 |
| Groundnut | $\$ 60.83$ | $[\$ 44.44, \$ 77.22]$ | 110 |
| Cowpeas | $\$ 51.17$ | $[\$ 24.56, \$ 77.79]$ | 15 |
| Beans | $\$ 51.00$ | $[\$ 38.39, \$ 63.6]$ | 148 |
| Sweet Potatoes | $\$ 46.22$ | $[\$ 37.95, \$ 54.48]$ | 76 |
| Cassava | $\$ 43.47$ | $[\$ 34.65, \$ 52.3]$ | 352 |
| Sorghum | $\$ 39.61$ | $[\$ 28.8, \$ 50.42]$ | 150 |
| Millet | $\$ 35.06$ | $[\$ 27.58, \$ 42.54]$ | 69 |

| Short Rainy Season Land Productivity by Primary Crop Planted on Plot |  |  |  |
| :--- | :--- | :--- | :--- |
|  | Mean (USD/Acre) | $95 \%$ C.I. | Observations |
| Yams | $\$ 202.36$ | $[\$ 90.74, \$ 313.98]$ | 3 |
| Paddy | $\$ 196.68$ | $[\$ 106.76, \$ 286.59]$ | 43 |
| Sweet Potatoes | $\$ 74.96$ | $[\$ 31.46, \$ 118.45]$ | 28 |
| Sorghum | $\$ 53.91$ | $[\$-7.18, \$ 114.99]$ | 11 |
| Cassava | $\$ 49.69$ | $[\$ 26.28, \$ 73.1]$ | 109 |
| Beans | $\$ 48.41$ | $[\$ 35.63, \$ 61.19]$ | 86 |
| Maize | $\$ 47.26$ | $[\$ 37.15, \$ 57.37]$ | 385 |
| Groundnut | $\$ 39.30$ | $[\$ 22.66, \$ 55.94]$ | 21 |
| Millet | $\$ 22.19$ | $[\$ 10.04, \$ 34.35]$ | 5 |
| Cowpeas | $\$ 13.75$ | $[\$ 3.65, \$ 23.85]$ | 16 |

| Long Rainy Season Labor Productivity by Primary Crop Planted on Plot |  |  |  |
| :--- | :--- | :--- | :--- |
|  | Mean (USD/Work Day) | 95\% C.I. | Observations |
| Paddy | $\$ 2.25$ | $[\$ 1.83, \$ 2.67]$ | 470 |
| Cowpeas | $\$ 2.18$ | $[\$ 0.35, \$ 4]$ | 15 |
| Maize | $\$ 1.82$ | $[\$ 1.64, \$ 1.99]$ | 1538 |
| Yams | $\$ 1.63$ | $[\$ 0.51, \$ 2.75]$ | 15 |

| Sorghum | $\$ 1.28$ | $[\$ 0.03, \$ 2.52]$ | 11 |
| Maize | $\$ 1.26$ | $[\$ 0.98, \$ 1.54]$ | 383 |
| Cassava | $\$ 1.15$ | $[\$ 0.58, \$ 1.73]$ | 108 |
| Beans | $\$ 1.08$ | $[\$ 0.76, \$ 1.4]$ | 85 |
| Groundnut | $\$ 0.88$ | $[\$ 0.49, \$ 1.27]$ | 21 |
| Cowpeas | $\$ 0.83$ | $[\$ 0.47, \$ 1.18]$ | 14 |
| Millet | $\$ 0.14$ | $[\$ 0.03, \$ 0.25]$ | 4 |

## Appendix J Household Land and Labor Productivity by Gender of Household Head

| Land Productivity for Male- and Female-Headed Households (USD/Acre) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Household Head | Mean <br> (USD/Acre) | 95\% C.I. | No. of Observations | Wald test P -value |
| Long Rainy Season | Male | \$53.85 | [\$49.28, \$58.41] | 1,425 | 0.56 |
|  | Female | \$51.72 | [\$44.97, \$58.47] | 455 |  |
| Short Rainy Season | Male | \$37.78 | [\$30.04, \$45.52] | 463 | 0.65 |
|  | Female | \$42.25 | [\$22.92, \$61.59] | 125 |  |
| Fruit | Male | \$34.87 | [\$27.49, \$42.25] | 917 | 0.55 |
|  | Female | \$39.30 | [\$25.41, \$53.20] | 249 |  |
| Permanent Crops | Male | \$33.91 | [\$27.21, \$40.61] | 752 | 0.56 |
|  | Female | \$37.00 | [\$27.13, \$46.87] | 209 |  |
| All Seasons (Crops) | Male | \$95.89 | [\$86.82, 104.95] | 1,646 | 0.62 |
|  | Female | \$92.53 | [\$80.08, 104.98] | 524 |  |
| All Seasons (crops \& livestock byproducts) | Male | \$125.73 | [\$111.38, \$140.08] | 1,648 | 0.55 |
|  | Female | \$117.75 | [\$94.13, \$ 141.38] | 522 |  |

| Labor Productivity for Male- and Female-Headed Households (USD/Work day) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Household <br> Head | $\begin{aligned} & \text { Mean } \\ & \text { (USD/Acre) } \end{aligned}$ | 95\% C.I. | No. of Observations | Wald test P-value |
| Long Rainy Season | Male | \$1.79 | [\$1.62, \$1.96] | 1,426 | 0.13 |
|  | Female | \$1.58 | [\$1.33, \$1.84] | 456 |  |
| Short Rainy Season | Male | \$1.34 | [\$1.01, \$1.66] | 451 | 0.84 |
|  | Female | \$1.39 | [\$0.90, \$1.89] | 124 |  |

+ A value lower than the critical p-value of .05 (or .01 ) is necessary to confidently reject the null hypothesis that the difference between male and female headed households is zero.

## Appendix K Plot Land and Labor Productivity by Gender of Decision-Maker

| Land Productivity for Male, Female, and Shared Decision Making |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean Productivity (USD/Acre) | 95\% C.I. | Observations | Wald test P -value |
| Long Rainy Season | Male | \$69.82 | [\$62.5, \$77.14] | 1230 | 0.3069 |
|  | Female | \$65.49 | [\$58.29, \$72.68] | 773 |  |
|  | Shared | \$72.57 | [\$65.7, \$79.43] | 1338 |  |
| Short Rainy Season | Male | \$58.86 | [\$42.6, \$75.12] | 202 | 0.7319 |
|  | Female | \$58.17 | [\$41.08, \$75.26] | 159 |  |
|  | Shared | \$52.40 | [\$34.12, \$70.69] | 255 |  |
| Permanent Crops | Male | \$68.25 | [\$46.42, \$90.08] | 426 | 0.7797 |
|  | Female | \$59.61 | [\$44.16, \$75.07] | 247 |  |
|  | Shared | \$64.52 | [\$47.64, \$81.4] | 528 |  |
| Fruit | Male | \$60.89 | [\$49.26, \$72.53] | 468 | 0.3092 |
|  | Female | \$70.82 | [\$49.86, \$91.77] | 279 |  |
|  | Shared | \$76.93 | [\$58.09, \$95.78] | 558 |  |
| All Crops | Male | \$111.49 | [\$99.44, \$123.54] | 1492 | 0.3218 |
|  | Female | \$105.43 | [\$93.63, \$117.23] | 905 |  |
|  | Shared | \$118.19 | [\$104.37, \$132] | 1592 |  |

| Labor Productivity for Male, Female, and Shared Decision Making |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Appendix T Comparison of Area Harvested and Area Planted Yield Calculations

To calculate the area planted for the denominator in our yield calculations for the long and short rainy seasons, the plot size was multiplied by the percentage of the plot cultivated with the crop. This calculation includes areas of plots that were cultivated but had no harvest as a result of destruction and the full planted area of plots that were not fully harvested due to a variety of reasons (see Sections Plots with Area Harvested Less than Area Planted, Entire Plots not Harvested due to Destruction, and Portions of Plots not Planted due to Constraints for information on how many plots were affected by these factors and their causes).

The area harvested for each crop in the long and short rainy seasons is the response to a direct question in the survey (What was the area harvested in the long rainy season 2008/Last completed short rainy season?).

These questions were not asked for fruit and permanent crops. Therefore, the area planted yield calculations for fruit and permanent crops include the entire plot size of each plot planted with the crop. If the respondent indicated a harvest of zero kilograms, the value of zero was not included unless that respondent also reported pre-harvest losses. In the area harvested calculations, all values of zero were counted as missing data. To compensate for the lack of information on the area planted with permanent crops, two yield estimates were calculated: one assuming that the entire plot was planted with each crop and another that assumes half the plot was planted with each crop. Both of these yield estimates are reported in Appendix $S$.

## Appendix U Explanation of Plot, Household, and Country level Calculations

The yield measures as well as land and labor productivity were all calculated at the plot, household, and country level, producing different descriptive statistics at each of these levels. The different calculations allow analysis of variables that may affect yields and productivity at different levels. For example, it would be impossible to examine the relationship between yields and gender of plot decision-maker if we did not calculate yields at the plot level. However, it makes more sense to examine yields for an entire household and not by plot when examining the relationship between yields and the gender of the household head. Country level estimates can be used to distinguish between different seasons and years.

Figure 69 (below) shows an example of how yield figures can differ when calculated at the different levels. This example imagines a country with only three households. Two households cultivate maize on two plots and one household cultivates maize on one plot. The average plot yield, household yield and country yield appear at the bottom of the figure ( $343 \mathrm{~kg} /$ acre, $310 \mathrm{~kg} /$ acre and $296 \mathrm{~kg} /$ acre respectively). Similarly to the actual observations, in this example smaller plots produce higher yields.

At the plot level, each plot counts as one yield observation, making five total observations. To calculate the average plot yield, the yield of each plot is added together and divided by five. The acreage is taken into account as the denominator when the yield is initially calculated, but when calculating the plot average, the $600 \mathrm{~kg} /$ acre yield of the half acre plot is counted as one observation and the $200 \mathrm{~kg} /$ acre yield of the two acre plot is also counted as one observation, even though the second plot is four times the size of the first. At the household level, the entire harvest for each household is divided by the total landholding size for that household. The resulting average yield is lower than the plot average yield. This finding is caused by averaging out the yields in households that have more than one plot. While Farmer A harvested a large amount of maize per acre on his smaller plot, when averaged with the more modest yield on his larger plot, his household average kilograms/acre is lower. There are only three observations at the household level - one for each household.

The country level adds up the amount harvested for every household in the country and divides by the total area harvested. Therefore, there is only one observation at the country level and smaller plots with higher yields do not have as large of an effect.

Figure 69: Example of Yield Calculations at the Plot, Household and Country Levels

## Appendix V Comparison of Plot Yields by Gender of Decision-Maker (area harvested)

| Season | Decision-Making | Average Yield (kg/acre) | 95\% C.I. | No. of Observations | Wald test Pvalue |

## Appendix Z Intercropping by Crop and Reasons for Intercropping

| Estimated Proportion of plots intercropped by crop planted, Long Rainy Season |  |  |  |
| :--- | :--- | :--- | :--- |
| Crop | Estimated proportion | 95\% C.I. | Observations |
| Cowpeas | $91 \%$ | $[86 \%, 96 \%]$ | 129 |
| Beans | $84 \%$ | $[78 \%, 89 \%]$ | 557 |
| Groundnut | $72 \%$ | $[66 \%, 78 \%]$ | 346 |
| Yams | $71 \%$ | $[44 \%, 99 \%]$ | 22 |
| Maize | $65 \%$ | $[61 \%, 68 \%]$ | 1864 |
| Sorghum | $63 \%$ | $[55 \%, 71 \%]$ | 273 |
| Sweet potatoes | $62 \%$ | $[53 \%, 72 \%]$ | 213 |
| Cassava | $46 \%$ | $[36 \%, 57 \%]$ | 207 |
| Millet | $45 \%$ | $[32 \%, 58 \%]$ | 110 |
| Paddy | $20 \%$ | $[14 \%, 26 \%]$ | 502 |

| Estimated Proportion of plots intercropped by crop planted, Short Rainy Season |  |  |  |
| :---: | :---: | :---: | :---: |
| Crop | Estimated proportion | 95\% C.I. | Observations |
| Yams | 100\% | - | 5 |
| Groundnut | 97\% | [93\%, 101\%] | 57 |
| Beans | 91\% | [86\%, 96\%] | 250 |
| Cowpeas | 91\% | [83\%, 100\%] | 41 |
| Sweet potatoes | 81\% | [75\%, 88\%] | 82 |
| Maize | 74\% | [ $68 \%, 80 \%$ ] | 400 |
| Sorghum | 58\% | [26\%, 90\%] | 16 |
| Millet | 41\% | [-6\%, 89\%] | 4 |
| Cassava | 40\% | [15\%, 64\%] | 45 |
| Paddy | 5\% | [-1\%, 10\%] | 47 |

| Estimated Proportion of plots intercropped by crop planted, Permanent Crops \& Fruit |  |  |  |
| :---: | :---: | :---: | :---: |
| Crop | Estimated proportion | 95\% C.I. | Observations |
| Cassava | 83\% | [79\%, 87\%] | 947 |
| Mango | 81\% | [76\%, 85\%] | 808 |

| Reasons for Intercropping |  |  |  |
| :--- | :--- | :--- | :--- |
|  | Estimated proportion | $95 \%$ C.I. | Observations |
| More fertile for soil | $4 \%$ | $[3 \%, 5 \%]$ | 121 |
| Substitute if either crop <br> fails | $82 \%$ | $[79 \%, 85 \%]$ | 2243 |
| Other | $8 \%$ | $[6 \%, 11 \%]$ | 218 |
| Combination of reasons | $6 \%$ | $[5 \%, 7 \%]$ | 151 |

## Appendix MM Yields Data Issues

| Issue | Description | Number of observations affected | Direction of effect | Magnitude of effect |
| :---: | :---: | :---: | :---: | :---: |
| Area Harvested and Planted Yield Calculations |  |  |  |  |
| Immature trees counted in fruit yield estimates. | Mango trees take up to 5 years to reach full production. The survey asks how many trees were planted in the past 12 months (s6aq4) and these trees have been removed from yield calculations. | Unknown, however 45 out of 630 observations reported planting the majority of trees in 2003 or later | Underestimate fruit yields | Unknown; when observations are removed of plots where the majority of trees were planted post 2003, average yield increases from 95 to 98 kg/tree |
| Inaccurate responses/recall | Many of the questions require respondents to give information that they may not know precisely or accurately remember (e.g. kilos of fruit harvested in the past 12 months or total estimated value of maize harvest in the long rainy season). | All responses subject to inaccuracies | Unknown; in the case of land size, overestimates yields because respondents tended to report smaller plots than those that were measured | Unknown |
| Area Harvested Yield Calculations |  |  |  |  |
| Area harvested reported as zero | Values of 0 acres for area harvested in the long rainy season (s4aq8) when a value is reported for amount harvested (s4aq15). These observations were therefore excluded from area harvested calculations. Note: this issue only occurs in the long rainy season data and not in the short rainy season data. | Total of $\mathbf{6 6}$ observations; largest effect on maize yields with 32 out of $\mathbf{1 , 8 5 9}$ observations | Unknown, but may overestimate yields; observations reporting zero acres harvested tended to produce more maize | Small: average maize quantity harvested including the 32 observations was 496 kg ; excluding the observations the average harvest was 500 kg . |
| Area harvested not reported for permanent crops | Respondents are not asked the area harvested for permanent crops or the number of trees harvested for fruit. Therefore, we have created two estimates for cassava; one assuming that the entire plot was harvested and one assuming that $50 \%$ was harvested. | Unknown, however an estimated proportion of $\mathbf{2 7 \%}$ plots growing cassava harvested less than the area planted in the long rainy season and $13 \%$ harvested less area than planted in the | Underestimate permanent crop cassava yields | Country level cassava yields for the long and short rainy seasons were 493 and 254 $\mathrm{kg} /$ acre respectively. For permanent crops the yields were 183 kg /acre under the assumption of harvesting the full plot and $288 \mathrm{~kg} /$ acre |

|  |  | short rainy season. |  | under the assumption of harvesting half of the plot. |
| :---: | :---: | :---: | :---: | :---: |
| Area Planted Yield Calculations |  |  |  |  |
| Percent of plot planted not recorded for permanent crops | Respondents were not asked how much of their plot they planted with a particular crop for permanent crops (cassava). | Unknown; however an estimated proportion of $\mathbf{2 7 \%}$ did not plant the entire plot with cassava in the long rainy season and $\mathbf{1 3 \%}$ in the short rainy season. | Underestimate permanent crop cassava yields | Country level yields for cassava area planted were 409 and $81 \mathrm{~kg} /$ acre for the long and short rainy season respectively. The average yield for permanent crop observations was 166 kg /acre assuming the entire plot was harvested and $263 \mathrm{~kg} /$ acre assuming half the plot was harvested |
| Crops that were planted but not harvested for unknown reasons | Respondents who did not harvest any of the crop planted were asked the reason that no crop was harvested (s4aq2 \& s4bq2); a large portion of the responses were "other". These observations were eliminated from the analysis. | Total of 204 observations in the long rainy season and 83 observations in the short rainy season, spread out amongst all crops (e.g. Maize long rainy season 74 observations out of 1,888 ) | Overestimate yields | Small due to the small number of observations |
| Area planted variables less than area harvested | In several cases the calculated area planted variable was smaller than the area harvested variable (s4aq8 and s4bq8) | For the case of maize long rainy season there are 114 observations out of 1909 where the area harvested is greater than the area planted. | Overestimate yields | The average difference between the two variables when the area planted was smaller was 0.39 acres. |

[^0]:    ${ }^{1}$ Tanzania has two major rainfall regions. The majority of the country has one long rainy season that typically lasts from December through April. The North and Northeastern parts of the country are bimodal: in addition to the long rainy season lasting from March through May, they also have a short rainy season characterized by lighter rainfall that lasts from October to December (Minot, N. (2010). Staple food prices in Tanzania. Washington, D.C. International Food Policy Research Institute).

[^1]:    * F-test shows statistically significant variation between zones at the .10 level
    ** F-test shows statistically significant variation between zones at the .05 level
    *** F-test shows statistically significant variation between zones at the .01 level

[^2]:    Question s4bq16

[^3]:    * F-test shows statistically significant variation between zones at the .10 level
    ** F-test shows statistically significant variation between zones at the .05 level
    *** F-test shows statistically significant variation between zones at the 01 level

[^4]:    ${ }^{2}$ Land productivity p-values range from .55 to .65 .

[^5]:    ${ }^{3}$ Labor productivity p-values are .13 and .84 for long and short rainy seasons respectively.

[^6]:    ${ }^{4} \mathrm{P}=.3218$. The difference in productivity between plots with female decision making and shared decision making were also not statistically significant as well as the difference between plots with female and male decision making.

[^7]:    ${ }^{5}$ Landholding size includes all plots owned and/or cultivated by a household.
    ${ }^{6} \mathrm{r}=-.187$ for landholdings of less than 15 acres and $\mathrm{r}=-.089$ for all landholding sizes ( $\mathrm{p}<.0001$ )

[^8]:    ${ }^{7}$ Prices were calculated by dividing the total value by the quantity sold

[^9]:    ${ }^{8}$ FAO yield estimates were pulled from FAOSTAT on June 6, 2011.
    ${ }^{9}$ The FAO calculates yield measures at the country level, using the total production divided by the total amount of land harvested. Using LSMS data, yields can be calculated at the plot and the household levels by dividing the quantity harvested by the area harvested and planted for each plot and for each household. http://faostat.fao.org/site/379/DesktopDefault.aspx?PageID=379

[^10]:    ${ }^{10}$ In order to include these factors in our analysis, we have created two different measurements for yields. One method mirrors the FAO by using the area harvested in the denominator of the yield calculation. The other method uses the area planted, which we calculated by multiplying the plot size by the percentage of the plot planted with the crop under analysis.

[^11]:    * Statistically significant at the .10 level

    Yield variables, sbmemno, \&o sbq2
    **Statistically significant at the .05 level
    ***Statistically significant at the .01 level
    $\dagger$ Insufficient observations to calculate reliable yield estimates for yams

[^12]:    * Statistically significant at the .10 level
    **Statistically significant at the .05 level
    ***Statistically significant at the .01 level
    $\dagger$ Insufficient observations to calculate reliable yield estimates for yams

[^13]:    ${ }^{11} \mathrm{r}=-0.0634, \mathrm{p}=0.007$
    12 Paddy LRS: $\mathrm{r}=0.0748, \mathrm{p}=0.0975$; cassava permanent crop observations: $\mathrm{r}=-0.163, \mathrm{p}=0.0001$

[^14]:    *Note: scatter plot is of un-weighted data and therefore is not nationally representative

[^15]:    *Note: scatter plot is of un-weighted data and therefore is not nationally representative

[^16]:    ${ }^{13}$ The options for response were "Not mine to harvest, Still in plot, Destruction and Other". There was no indication on what reasons could be meant by "Other". In the long rainy season, respondents reported 154 crops not harvested on a plot due to
    "Destruction" and 204 not harvested due to "Other". In the short rainy season there were 94 observations of "Destruction" and 83 observations of "Other". Due to the lack of information on the reasons for "Other" these responses were not included in this analysis. Responses of "Not mine to harvest and Still in plot" were also not included since the outcome of the harvest was unknown.

[^17]:    14 "Was divided" and "Other" were also listed as options, but have been excluded from this analysis as they are not necessarily constraints.

[^18]:    ${ }^{15}$ The meaning of 99 as a response for this question is not indicated anywhere on the survey, in the manual for enumerators, or in the data. However, the manual for enumerators does
